

Project: "Private Web application" (PART THREE)

Part Three: Database and Application Features

1. Database Creation:

- Create the database “privateschool” with the following tables:
 - **authentication**: Contains fields:
 - id
 - username
 - password
 - **admission**: Contains fields:
 - id
 - All fields from the admission form

2. Admission Form Processing:

- Complete the backend logic to process admission form submissions and insert the submitted data into the admission table.
- In the web site, display a confirmation message to the user that their admission request has been successfully registered.

3. Login:

- Add a login button to the website that directs users to a login page for authentication.
- Validate users based on the “**authentication**” table in the database.

4. Web Application Template:

- Download a free Bootstrap template specifically designed for web applications to manage the school’s administration system. Keep only the necessary pages and **delete all additional pages.**

5. Manage Admission Requests: The web application manages the admission requests of students who have applied through the school's website.

- Implement a page to display all admission requests submitted through the school’s website. Display the admission requests in a table with the following columns:
 - **First Name**
 - **Last Name**

- **Class Applying**

- **Actions**

- Add 4 buttons in the "Actions" column:

1. **Details:** Leads to a page displaying all the details of the admission request.
2. **Edit:** Leads to a page that contains a form, where the user can edit the admission request fields.
3. **Delete:** Deletes the admission request. Before deletion, display a confirmation message.

6. Implement proper validation for all form fields to ensure data integrity and prevent malicious inputs. This includes both front-end and back-end validation.

Optional: Use the Data Tables library (<https://datatables.net/>) to improve table pagination and filtering.
